PHOENIX Prototype: Twenty Intended Capabilities

Functions, practical importance, scope limits and implications for collaborative systems work

INTERNAL OWNER-REVIEW DRAFT • NOT SENT • NOT APPROVED FOR EXTERNAL RELEASE

Scope and status

This note describes the PHOENIX Foundation Alpha prototype specifically, not every proposed capability of the wider PHOENIX Platform. It retains the twenty headings and their order from John's supplied list. The headings overlap: the first ten are broad groups, while many of items 11–20 make particular safeguards or operating functions explicit. They are not a count of separate modules, screens or completed software features. [P1–P4]

Answer to the owner's capability question

Yes, at the level of intended capability areas, the twenty headings are substantially grounded in the Alpha requirements and WSS–Shaligram design discussion. That does not establish that all twenty are currently working, mutually accepted for the same delivery phase, or verified end to end. The FRD is marked Draft for WSS confirmation / To be Confirmed; the WSS response contains recommended decisions. Payment delivery is expressly tied to the signed scope, and later clarification is not automatically an accepted build freeze. [P1, document control and §1.2; P2 opening]

How the benefit language should be read

The supplied CEB GPT document explains the first ten capability groups. Its insights about moving from participation to legitimate decisions, coordinated action and learning are used here as explanatory framing. Each proposed benefit and climate or infrastructure example is an application rationale, not a measured PHOENIX result. Statements that these capacities guarantee success, that all are required in software on day one, or that other organizations cannot succeed without PHOENIX are not supported. [P3–P4; R1, evidence limitations]

What is foundational, and when

Authority, consent, visibility, human review and evidence traceability need to be proportionate to the activity being undertaken. They should be established before sensitive data is collected or consequential commitments are made. Matching, commercial access and AI may be optional or staged. Equivalent arrangements may already exist in collaborators' institutions or tools; the proposed value of this prototype is their governed connection, not exclusivity.

Twenty intended prototype capability areas

1. Identity, Role, and Authority Management

Intended prototype function. The PHOENIX Foundation Alpha prototype is being specified to distinguish a person's identity from their organizational membership, active context, role, authority, commercial access and consent. One person may have several roles without combining the permissions of different organizations or projects. Invitations, sensitive-role approval and scoped mandates are intended to make these distinctions visible and enforceable. A facilitator, reviewer, sponsor or technical administrator should not automatically inherit another role's powers.

Why it matters. This matters because being present in a collaboration is not the same as being entitled to commit an organization, approve evidence or authorize a consequential action. In an infrastructure or climate initiative, a researcher may explain evidence, a community representative may identify lived consequences, and an operator may accept delivery responsibilities. Clarifying those contributions can reduce mistaken commitments and unresolved accountability. Software can record and apply an authorized mandate; it cannot create the underlying institutional authority merely by assigning a label.

Source basis: P1 §§3.1–3.2, F01; P2 opening architectural rule and sensitive-role clarification.

2. Consent, Visibility, and Information Governance

Intended prototype function. The intended prototype separates agreement to participate from optional permissions for AI processing, research and evaluation, cross-organization sharing, public or funder release, and external exchange. Agreements are versioned, and record visibility is specific to the participant, context and permitted purpose. Organizational participation or sponsorship is not intended to expose private reflections, personal hurdles, protected support notes or AI conversations. An external-exchange consent choice is not evidence that a functioning external integration exists.

Why it matters. The practical benefit is collaboration without requiring people to surrender unrelated information. Researchers, operators, community groups and funders may need different information for legitimate purposes. Purpose-specific sharing can support their work while limiting unnecessary disclosure. For a community resilience project, for example, an agreed public finding can be shared without opening the personal discussion from which it arose. The need is to establish suitable information boundaries before sensitive information is collected, not to claim that every optional use must be enabled from the outset.

Source basis: P1 §§3.3, 4.5–4.6, F02; P2 optional-capability clarification.

3. Purpose, Profile, and Context Orientation

Intended prototype function. The prototype is intended to help participants describe their purpose, goal, needs and hurdles, retain control of profile changes, and identify an appropriate next step. Its Purpose Compass and bounded pathways connect reflection with practical participation. Profile claims carry provenance labels, and pathway activation requires participant acceptance. The home view identifies the active role and context and offers a rule-based next action rather than an AI ranking of what the person should do.

Why it matters. This can help collaborators understand what each person is seeking, offering and able to undertake, rather than relying on a job title or a few matching keywords. In a climate-related project, shared direction needs to connect to real circumstances, available capacity and agreed scope. The Alpha does not establish psychometric, purpose or coherence scores. It is not intended to diagnose people, rank their worth, or silently rewrite their identity. The useful foundation is explicit, revisable context and participant choice.

Source basis: P1 §§2.5, 3.1, 3.4–3.5, F03–F04; P2 pathway recommendation clarification.

4. Structured Collaboration and Relationship Formation

Intended prototype function. The prototype distinguishes three linked spaces: Circles for shared learning, sensemaking and deliberation; Rope Teams for mentoring, support and accountability; and Action Workspaces for agreed work and deliverables. These spaces are intended to remain separate, with their own histories, memberships and information boundaries. They can be linked without being converted into one another, and the demonstration journey is not a compulsory sequence for every participant.

Why it matters. This addresses the gap between meeting a potential collaborator and developing a workable relationship. A research discussion, a personal support conversation and a delivery meeting do not have identical purposes or confidentiality expectations. Keeping them connected but distinct can help a multi-organization team retain learning and trust while organizing action. Linking a support space to a project must not copy protected notes or automatically grant membership. The detailed conditions for formal return cycles remain a separate controlled requirements matter.

Source basis: P1 §§2.1–2.4, 3.6–3.9, F05; P2 collaboration-space clarification.

5. Needs, Assets, Offers, Opportunity Discovery, and Reviewed Matching

Intended prototype function. The prototype is intended to represent needs, assets and offers through Opportunity Cards with an audience and expiry, and to explain proposed connections through Match Briefs. PHOENIX-generated matches require steward review and mutual consent before contact details are released. A separate route is specified for known, authorized collaborators, subject to context, authority and acceptance checks. Alpha matching is bounded to PHOENIX records rather than comprehensive discovery of external organizations.

Why it matters. The potential benefit is making complementary capacity easier to find: a community's need, a researcher's method, an operator's knowledge, or an organization's available time and resources. For a heat-resilience or catchment initiative, the first useful step may be identifying who can contribute and who is missing. A suggested connection is not a commitment, verified expertise or an allocation of resources. Human review and participant choice remain necessary so that discovery does not become opaque assignment.

Source basis: P1 §§2.5, 3.8, F06; P2 matching-routes clarification.

6. Governed Deliberation and Decision Support

Intended prototype function. The Alpha Circle design includes private drafts, shared proposals, discussion, change history, voting, versioned committed proposals and items held for later consideration. AI may assist with advisory checks for missing sources, contradictions or uncertainty, but it does not determine a vote or approve a decision. Equal voting weight applies to eligible members in the specified Circle process; it should not be presented as a universal decision rule for every organization.

Why it matters. This capability is intended to help people think together before they act together. Infrastructure and climate decisions may involve competing priorities, uncertain evidence and consequences that fall on different groups. A structured process can make alternatives, concerns, authority and the adopted result easier to understand and revisit. The aim is not to manufacture agreement or replace institutional governance. A discussion summary, an AI recommendation and an authorized human decision must remain different things.

Source basis: P1 §§3.6, 3.16, F05 and F09.

7. Action and Project Coordination

Intended prototype function. The intended Action Workspace connects a charter and origin with scoped roles, tasks, owners, milestones, dates, resources, dependencies, risks, issues, decisions and evidence. A task cannot become In Progress until its assignee accepts it. AI may propose a roadmap or tasks as a draft, but the team accepts, edits or rejects the proposal; AI does not assign or reassign people's work. Change Objects provide a versioned record of intended change requiring human approval.

Why it matters. This helps turn a promising discussion into bounded, accountable work. In a cross-organizational initiative, a decision is useful only when the relevant people can accept responsibilities and understand what depends on what. For a community energy example, participants might coordinate evidence gathering, operator review and a defined next decision without pretending that the software controls physical assets. A changed goal should not silently become someone's acceptance of changed work. Resources, authority and real-world delivery capacity still have to exist outside the software.

Source basis: P1 §§3.9–3.10, FR-F07-01–14 and FR-F07-16; P2 collaboration clarification.

8. Governed Records, Evidence, and Metrics

Intended prototype function. The prototype is intended to link claims and milestones to source records, provenance, reviewers and stated limitations. Evidence support level, review outcome, confidentiality, lifecycle and release permission are separate dimensions. An approved item is not automatically strong evidence of every claim or cleared for every audience. The Alpha starter dashboard measures platform learning, including review turnaround and movement from conversation to action, rather than demonstrating social or environmental impact.

Why it matters. This distinction is fundamental to credible research and responsible reporting. Meetings held, tasks completed and people enrolled are not equivalent to reduced emissions, improved flood resilience or better service outcomes. For an ISR-related collaboration, domain measures would need their own agreed definitions, baselines, native units, confidence and evidence. The supplied indicator guidance also distinguishes review scores from targets. The prototype could support the handling of that evidence, but automatic cross-case synthesis or validated climate-impact measurement is not established by this capability heading.

Source basis: P1 §§3.11–3.14, F08; R2 §§3–6; R3 §§2–3 and 8.

9. Learning, Correction, and Adaptive Improvement

Intended prototype function. The Learning Harvest is intended to assemble what happened, what worked, what did not and what should be considered next. Its design allows dissent and negative findings, optional AI drafting, authorized human completion and a separate release decision. Incident and rights workflows provide human review, remedy and reconsideration routes. A Harvest can produce a candidate profile update only under the applicable attribution and participant-approval rules; team conflict must not become an automatic individual assessment.

Why it matters. This provides a way to retain learning rather than lose it after a project milestone or change of personnel. Complex projects may reveal incorrect assumptions, delayed effects or overlooked harms. Recording those findings can inform a proposed correction while preserving the authority needed to adopt it. In climate or infrastructure work, the useful question is not simply whether a plan was followed, but whether observed results justify continuing, adapting or stopping. Learning does not itself authorize a new cycle, public disclosure or automatic modification of commitments.

Source basis: P1 §§3.13, 3.18, F08 and F11; R1 Action 6; R3 §§7–8.

10. Bounded AI and Configurable Platform Operations

Intended prototype function. The intended prototype combines governed AI assistance with configurable packs, templates, terminology, onboarding, resources and workflow options. Administrators are intended to adapt an experience within an approved envelope rather than commission a separate product for each setting. Consent semantics, protected permissions, evidence meanings and safety rules are not ordinary local configuration. Configuration restoration must not delete participant records. Core manual workflows are intended to remain available when AI is declined or unavailable.

Why it matters. The benefit is local usefulness without losing common safeguards. A research group, community initiative or mentoring program may need different language and entry points while sharing the same responsibility for consent, review and traceability. This is not a promise of unrestricted customization, autonomous specialist agents or production-scale federation. The foundational requirement is a clear distinction between what may vary locally and what must remain protected. Whether a new pack can actually be created through the administrative interface still requires an authorized, build-specific demonstration.

Source basis: P1 §§2.5, 3.15, 3.20, F09 and F12; P2 configuration clarification.

11. Consent Control and Withdrawal

Intended prototype function. This capability concerns changing a permission after it has been granted. The Alpha requirements call for independent withdrawal of optional purposes, stopping new affected use, canceling queued AI requests and restricting affected derivatives and search caches pending review, while preserving appropriate audit history. Declining or withdrawing an optional permission should not unnecessarily remove unrelated core participation.

Why it matters. This matters because trust depends on continuing choice, not a single onboarding checkbox. A participant who agreed to research use may later reconsider without wishing to abandon the entire collaboration. Withdrawal must have understandable consequences and a human route for questions. It should not be described as guaranteed erasure of every copy previously distributed outside the platform; the actual scope of restriction, retention, correction and deletion must be reported truthfully. For research partnerships, these conditions should be settled before identifiable information is reused.

Source basis: P1 F02, including withdrawal requirements; P1 §§3.3 and 3.18.

12. Matching Transparency

Intended prototype function. The intended Match Brief explains the reason for a proposed connection, the source information used, gaps, uncertainty, and relevant consent, authority and readiness status. A steward's review is not a replacement for either participant's decision. The Alpha does not permit payment to determine match inclusion or order, and a declined introduction must not release contact details.

Why it matters. Transparency helps a person judge an opportunity rather than merely receive a recommendation. A researcher and a community group may appear well matched while having different timetables, capacities or expectations. Making those uncertainties explicit can prevent wasted effort and inappropriate introductions. Matching should not be presented as a verdict on someone's value, trustworthiness or suitability. Discovery proposes a possibility; transparency gives people a basis for deciding whether to explore it.

Source basis: P1 §3.8 and F06, including AC-F06-01–04.

13. Decision Records and Accountability

Intended prototype function. The prototype is intended to retain versioned proposals, committed decisions, approvals, responsibilities and relevant change history. Its review inbox brings authorized human decisions into a visible queue, while Action Workspaces connect those decisions to commitments and evidence. The record should distinguish what was proposed, what was adopted, who had the authority, and what subsequently occurred.

Why it matters. This supports continuity across organizations and over time. When an infrastructure recommendation changes, collaborators need to know which version was agreed, what information informed it and whether existing commitments were reconsidered. A recorded approval does not prove implementation, and implementation does not establish beneficial impact. Keeping these stages distinct can help resolve disagreement without reducing accountability to blame. Actual organizational mandates remain outside the power of the platform to invent.

Source basis: P1 §§3.6, 3.9–3.10, 3.16; F05 and F07.

14. Communication Connected to the Work

Intended prototype function. The prototype is intended to connect communication to the proposal, opportunity, task, milestone or evidence record it concerns. The Alpha includes threaded Circle discussion with attachments, contextual opportunity responses and shared workspace updates, with issues escalated to an appropriate human role. Visibility remains tied to the underlying context.

Why it matters. The benefit is less separation between a conversation and the action it is meant to inform. A question about an indicator can stay connected to the evidence and decision, rather than become an isolated message that later participants cannot interpret. This can help research and delivery teams preserve assumptions and avoid treating informal discussion as an accepted commitment. Alpha scope should not be expanded by implying real-time chat, videoconferencing, or Zoom and Teams integrations; those are not established features of the specified prototype.

Source basis: P1 §§2.5, 3.6, FR-F06-13 and FR-F07-16.

15. Document and Information Management

Intended prototype function. The intended records repository retains documents and links with version history, retention settings and Record Passport-lite governance metadata. A source can be referenced from several work items without creating competing copies. Upload validation, malware scanning and quarantine are specified requirements, not certifications that the current build has passed those controls. Source permissions remain attached to the record.

Why it matters. This can help researchers and project teams know which evidence version informed a decision and where a correction belongs. It is especially useful when technical assessments, stakeholder observations and project records change at different times. Linking a document to another activity should not disclose its contents to everyone in that activity. The foundation is traceable, permission-aware information handling, not the assumption that collecting more documents automatically creates reliable knowledge or interoperable external databases.

Source basis: P1 §3.11, F08 and FR-F06-14.

16. Practical AI Assistance

Intended prototype function. The specified AI functions support bounded preparation: summaries, drafts, pathway suggestions, proposed tasks and advisory checks for missing sources, contradictions or uncertainty. Outputs are labeled as AI, identify sources and uncertainty, and remain subject to the relevant human review. Advisory fact-checking is restricted to the approved source registry rather than an unrestricted search across external repositories.

Why it matters. This could reduce the burden of preparing a discussion or comparing supplied information while leaving interpretation and responsibility with people. A research team might use an authorized summary to prepare for a review, then check it against the underlying material. An AI task proposal is not an accepted assignment; an evidence check is not approval; a summary is not proof of consensus. AI is an optional aid, not a demonstrated prerequisite for every successful climate or infrastructure collaboration.

Source basis: P1 §3.15, FR-F07-05–09 and FR-F09-01–11.

17. AI Access Controls and Human Review

Intended prototype function. The Alpha specifies an AI Gateway that checks identity, role, context, consent, sensitivity, authority, source permissions and policy before retrieval. It distinguishes private assistance, workflow drafts and consequential releases. Workflow drafts require human editing or review; consequential release also requires a versioned release decision and a correction route. The specification prohibits participant-data use for model training and prevents AI outputs from determining votes, approvals or releases.

Why it matters. These controls are necessary whenever AI is introduced into a permissioned collaboration. Information must not become available to AI simply because it might improve an answer. Researchers and communities need to understand which material may be processed and who decides whether an output can be relied on or shared. These are requirements to verify in the selected build, not guarantees inferred from the design. A safe collaboration also needs a usable non-AI route.

Source basis: P1 F09, especially FR-F09-02–08 and AC-F09-01–03.

18. Paid, Sponsored, and Free Access

Intended prototype function. The design discussions include paid products, sponsored seats, institutional arrangements and approved free access. Commercial entitlements are intended to remain distinct from membership, role, mandate, consent and record access. The FRD states that delivery of payment functionality depends on the phase set by the signed statement of work. It excludes tokens, staged project-funding commitments and funding reallocation from Alpha.

Why it matters. The potential benefit is participation supported through different funding arrangements without allowing payment to purchase governance authority or private information. A sponsor could fund seats while receiving only approved reporting. This may help a collaboration include participants who cannot pay, but affordability and inclusion are not demonstrated simply because a seat model is specified. Exact prices, approved products, billing readiness and launch timing require confirmation. A general grant-management, escrow or automated fund-disbursement system must not be implied.

Source basis: P1 §3.17 and F10; P2 sponsor/funder and membership clarifications.

19. Invitations and Notifications

Intended prototype function. The intended invitation process identifies a context, nominated role and validity period, with single-use links, expiry, revocation and reuse of an existing identity when a further role is added. Notifications are specified to connect people with relevant work and review needs. Receiving an invitation or notification does not itself establish unrestricted access to the associated records.

Why it matters. This helps people enter the right collaboration and notice the decisions or actions that need their attention. For distributed research and delivery teams, a missed review request can delay dependent work. Notifications should nevertheless protect sensitive content, explain their context and take the recipient only to an authorized view. Actual email delivery and reliable end-to-end behavior must be demonstrated in the selected environment; a screen or requirement describing notifications is not proof that external delivery works.

Source basis: P1 §3.2, F01 and F12.

20. Action Tracking and Audit Trails

Intended prototype function. The prototype is intended to make task progression and consequential operations reviewable through linked work records and audit events. Relevant records include accepted tasks, decisions, evidence review, role and entitlement changes, configuration actions and AI suggestion lineage. The audit trail should support an account of what was requested, what was authorized, and what is known to have happened, without confusing a pending or unknown outcome with success.

Why it matters. This can help collaborators identify where follow-through stopped and understand a correction without relying solely on memory. For a climate initiative, it may show that an agreed monitoring task was accepted and evidence submitted; it does not by itself prove an ecological improvement. Auditability should be proportionate and access-controlled, not a justification for unrestricted surveillance. Private narratives and sensitive support records must remain within their proper boundaries while appropriate operational evidence is retained.

Source basis: P1 F01, F07–F10, F12, and non-functional audit requirements.

How the capabilities could work together

Illustration only, not an implemented ISR integration: collaborators select a bounded climate-adaptation question, establish who may decide and what information may be shared, and bring permitted evidence into a Circle. They review alternatives, record an authorized decision, and invite participants to accept tasks in a linked Action Workspace. Evidence review and a Learning Harvest then support reconsideration of results, uncertainties and unintended effects. AI may assist permitted preparation; it does not supply authority, establish causal impact or publish findings.

Architecture, interfaces and expert collaboration

Architecture: connect records without merging authority

Candidate design review should trace a decision from its question, context, source version and human authority to accepted work, evidence and reconsideration. Identity, membership, role, consent, commercial entitlement and record permission must remain distinct. Connections between Circles, Rope Teams and Action Workspaces should preserve separate histories and protected content. These points describe review priorities; they do not amend any canonical model or authorize implementation. [P1–P2]

Interfaces: distinguish proposal, acceptance and result

The interface should make the active context visible and distinguish recommendations, adopted decisions, accepted tasks and known outcomes. It should explain when review is needed and retain usable refusal, correction and manual routes. A successful-looking screen must not substitute for evidence that an operation completed. The prototype's role-specific home and review-inbox requirements provide starting points; a new ISR-specific screen set has not been agreed. [P1 §§3.1, 3.16 and 5.13]

Dashboards: avoid confusing activity with impact

A candidate ISR-facing view could distinguish platform workflow, project delivery, evidence confidence and real-world outcomes. System health, service performance, societal outcomes and governance-selected targets should not be collapsed into a single score. Any implementation would require an agreed mapping of the collaborators' indicator definitions and permissions. The seven outcome-oriented review indicators and the seven success factors are different instruments, with different purposes and scales; neither becomes an Alpha feature merely by being discussed. [P1 §3.14; R2–R3]

User information: collect what the decision requires

For a bounded worked example, agree a minimum record: purpose, relevant context, authorized role, information-sharing conditions, question, system boundary, source and version, evidence limitation, decision owner, accepted action, dependency and review point. Where an indicator is used, record its native measure, unit where applicable, baseline or comparator, assessment date, confidence and evidence note. Do not collect personal reflections or sensitive narratives simply because they might be useful later. These are proposed requirements for review, not an assertion that all fields exist in the current build. [P1 F02 and F08; R2–R3]

Collaboration with researchers, systems and cybernetics experts

A useful division of contribution is to invite researchers to challenge evidence and attribution, systems specialists to examine boundaries and dependencies, cybernetics experts to examine feedback and delayed consequences, and practitioners and affected communities to assess usability and lived effects. These are proposed review contributions, not appointments or commitments. Gary's frameworks may offer conceptual lenses, but automatic diagnosis of individuals, relational scoring and planetary-scale monitoring are not imported into Alpha by this proposal. [R1; R4–R5]

What this note does not establish

Implementation evidence

No prototype was launched or tested during this document-production task. No current executable package, signed acceptance record or complete end-to-end feature verification has been established here. Prior assistant statements in the supplied transcript about local evidence are not reproduced as newly verified facts.

Explicit Alpha exclusions

The FRD boundary excludes digital twins, production-scale federation, external organization discovery, partner data exchange, unrestricted specialist/autonomous agents, token systems and direct institutional integrations beyond stated deep links. It also distinguishes starter platform-learning signals from advanced longitudinal metrics. These exclusions cannot be removed by persuasive outreach language. [P1 §2.5]

Material reconciliation points

The FRD describes invitation-only onboarding, while the October 16 WSS response proposes sponsor self-registration. Its advanced-sponsorship boundary also needs reconciliation with the later proposal for bounded sponsor-originated opportunities. No resolution or mutual vendor acceptance is inferred. The outreach therefore makes no promise of self-service sponsor entry or a funding-opportunity engine. [P1 §§2.5, 3.2 and F10; P2 Sponsor/Funder Role]

Release and rights

These files are for John’s internal review. Nothing has been sent to Gary Smith, Mark Enzer, Shaligram, Session B or Session C. The source materials’ current release permissions, the approved build description and the exact governing-document edition must be confirmed before external circulation. No third-party logos, screenshots, private contact details or substantial quotations are reproduced.

Source notes for owner review

These notes identify the material used to prepare the draft. Source inclusion is not external-release clearance, an endorsement, or evidence of product acceptance. Benefits and worked examples are independently drafted interpretations.

[P1] Shaligram Infotech LLP. PHOENIX FOUNDATION ALPHA — Functional Requirements Document, v1.0, Draft for WSS confirmation / To be Confirmed. Cover dated 6 October 2026; document-control row dated 2 October 2026. Exact file: PHOENIX FOUNDATION ALPHA - Functional Requirement Document (1).docx. Sections and requirement identifiers are used rather than relying on varying page layouts. This is evidence of stated requirements, not signed scope or completed implementation.

[P2] World Systems Solutions. PHOENIX_Product_Flow_Prototype_Review_Questions_Responses_WSS_16102026(1).docx, dated 16 October 2026, responding to Shaligram questions dated 14 October. Describes recommended Alpha decisions and clarifications. Recommendations are not assumed mutually accepted or incorporated.

[P3] Phoenix Capabilities 20.docx, supplied by John. Source of the twenty exact headings and their order; the file contains no implementation-status evidence.

[P4] CEB GPT on What's So Great About the Top 10 WSS Capabilities.docx, supplied by John. AI-generated explanatory commentary covering the first ten groups. Used for benefit framing only; not independent evidence of specification, implementation or impact.

[R1] Infrastructure Systems Review, Version 2.1, 13 October 2026. Supplied review draft; cover states planned publication on 11 February 2027. Used as the principal ISR version, not as a published or adopted policy. Relevant sections: reviewer notes, executive summary, Actions 1–7 and evidence limitations.

[R2] Connective Indicators and Metrics Briefing V2 (1).docx. Supplied FM3 briefing. Relevant sections: 3–6, distinguishing system of interest from stewardship and health, service, outcome and governance measurement. Its full framework is not presented as an implemented Alpha dashboard.

[R3] Outcome-Oriented Performance Indicators — Essential assessment guidance for case-study leads, dated 3 June 2026. Supplied guidance. Relevant sections: 2–3 and 7–8. Native evidence, review score and confidence are distinct; the indicators are not targets.
